

Independent Verification — §11.4.165

findings → fixes (round marker)

Run-id: 20260623-indep-verif-gate **Anchor:** §11.4.165 (Universal Independent Verification Agent Mandate) **Reviewer seam:** structurally separate from the author per §11.4.70 / §11.4.20 (the conductor reviews subagent output; the §1.1 paired-mutation machinery in `tests/meta/lib_metatest.sh` is the mechanical, author-independent verifier of every pre-build gate).

This file is the standing **independent-review findings → fix marker** that the CM-INDEPENDENT-VERIFICATION-AGENT pre-build gate asserts is present. Its existence + non-emptiness is mechanical evidence the independent-verification STEP ran for a substantive batch and produced a *verifiable artifact* (a real finding that was fixed), not a rubber stamp.

Findings → Fixes captured this round (and prior round, still live)

#	Finding (by independent verifier)	Fix landed	Source-anchored proof
F1	<code>tests/meta/lib_metatest.sh</code> restore-integrity check was tautological — it compared the restored file against the just-copied backup (file==backup after cp always matches), so a corrupted backup would pass silently (a §11.4 bluff in the very bluff-proofing machinery).	Capture the ORIGINAL sha256 at mutate-time (MT_MUT_ORIG_SHAS) + verify the restored file against THAT; FAIL fatally (exit 90) on any mismatch or missing shasum.	<code>tests/meta/lib_metatest.sh</code> lines 470-79, 93-94 carry the lite independent-review finding citation + the ex fatal path.
F2	CM-INDEPENDENT-VERIFICATION-AGENT functional gate (§11.4.165) was NOT	Add the functional gate to <code>tests/pre_build_verification.sh</code> + a paired §1.1 meta-test <code>tests/meta/meta_test_independent_verification.sh</code> .	This batch — gate + meta (mutate→FAIL→restore— captured in this dir).

#	Finding (by independent verifier)	Fix landed	Source-anchored proof
	implemented — only the anchor-presence propagation gate existed, so no mechanical assertion that the review STEP ran or that its machinery is wired.		

Honest boundary (§11.4.6)

The gate this marker backs mechanically asserts: 1. the independent-review **machinery is wired** (`lib_metatest.sh` present, executable, carries the structurally-separate review seam: the fatal restore-integrity abort that catches a bluff), AND 2. a substantive batch carries an **independent-review findings** → **fix marker** (this file).

It does **NOT** mechanically prove the human/agent reviewer was *independent of the author* (an irreducibly social property — enforced by the §11.4.70/§11.4.20 subagent-driven seam, not by a `grep`) NOR that the reviewed code is correct (that rests on each item's own §11.4.108 runtime-signature + §11.4.40 retest). It proves the review STEP ran and produced a verifiable artifact — the exact thing that distinguishes a real review from a stamp, and the gap the propagation gate left open.
