

QA evidence — rollout pgx StoragePort

Field	Value
Run id	20260608-rollout-pgx-storageport
Feature	rollout.PostgresStore — pgx-backed engine.StoragePort for the staged-rollout engine (production persistence)
Date	2026-06-08
Evidence	<u>run.log</u> — <code>real go test -tags integration -count=1</code>

What this proves (anti-bluff, Constitution §11.4)

- A **real PostgreSQL** is booted on-demand via the containers submodule on podman (boot summary: `started=1 failed=0`) — never a manual step, never a fake.
- The pgx PostgresStore passes the **same** runStorageScenario the in-memory store passes (shared helper), proving brick-port parity: `create` → `start` (with a persisted Load round-trip of state + the immutable 2-phase plan) → `healthy advance` → `healthy complete`, and an independent rollout HALTs on an error breach — all read back from the DB.
- Distinct host port (55445) from the store integration test (55432) so both integration packages boot concurrently under `go test -tags integration`.

Reproduce

```
cd server
go test -tags integration -count=1 ./internal/rollout/ -run
TestPostgresStoreScenario_Integration -v
```

Requires podman/docker + `podman compose`. Compose file: `server/deploy/postgres-rollout.compose.yml`.
